Roadmap

Part 1: Deflating eigenvalues from a small tridiagonal matrix.

$$\begin{bmatrix} Q_m^T \end{bmatrix} \begin{bmatrix} \text{tridiagonal} \\ T_m \end{bmatrix} \begin{bmatrix} Q_m \end{bmatrix} = \begin{bmatrix} \text{green square} & T_k \\ \text{red diagonal} & \Theta_{m-k} \end{bmatrix}$$

Part 2: An application: The equivalence of thick and implicit restarting in Lanczos.

Introduction – Tridiagonal Deflation

Let T_m be an $m \times m$ symmetric tridiagonal matrix: $T_m = \begin{bmatrix} & & & \\ & \text{---} & & \\ & & \text{---} & \\ & & & \text{---} \\ & & & & \end{bmatrix}$.

Compute the eigenpairs $\{(\theta_i, y_i)\}_{i=1}^m$ of T_m , and sort into two sets:

$$\underbrace{T_m Y_k = Y_k \Theta_k}_{\text{desired}}$$

$$\underbrace{T_m Y_{m-k} = Y_{m-k} \Theta_{m-k}}_{\text{undesired}}$$

Introduction – Tridiagonal Deflation

Let T_m be an $m \times m$ symmetric tridiagonal matrix: $T_m = \begin{bmatrix} \text{---} \\ \text{---} \\ \text{---} \end{bmatrix}$.

Compute the eigenpairs $\{(\theta_i, y_i)\}_{i=1}^m$ of T_m , and sort into two sets:

$$\underbrace{T_m Y_k = Y_k \Theta_k}_{\text{desired}}$$

$$\underbrace{T_m Y_{m-k} = Y_{m-k} \Theta_{m-k}}_{\text{undesired}}$$

Goal: Find an orthogonal matrix Q_m such that

$$\begin{bmatrix} Q_m^T \end{bmatrix} \begin{bmatrix} \text{---} \\ \text{---} \\ \text{---} \\ T_m \end{bmatrix} \begin{bmatrix} Q_m \end{bmatrix} = \begin{bmatrix} \text{---} \\ \text{---} \\ \text{---} \\ \begin{matrix} \text{---} T_k \\ \text{---} \Theta_{m-k} \end{matrix} \end{bmatrix}$$

Arrowhead Matrices

Goal:

$$\begin{bmatrix} Q_m^T \end{bmatrix} \begin{bmatrix} \diagup \diagdown \\ T_m \end{bmatrix} \begin{bmatrix} Q_m \end{bmatrix} = \begin{bmatrix} \text{green square} & T_k \\ \text{red arrowhead} & \Theta_{m-k} \end{bmatrix}$$

Our insight is a special *arrowhead matrix* created from the k desired eigenpairs (θ_i, y_i) :

$$D_{k+1} = \begin{bmatrix} \theta_1 & & & \beta y_{m,1} \\ & \ddots & & \vdots \\ & & \theta_k & \beta y_{m,k} \\ \beta y_{m,1} & \dots & \beta y_{m,k} & \star \end{bmatrix} \quad (\beta \neq 0, \star \in \mathbb{R}).$$

Arrowhead Matrices

Goal:

$$\begin{bmatrix} Q_m^T \end{bmatrix} \begin{bmatrix} \text{diagonal lines} \\ T_m \end{bmatrix} \begin{bmatrix} Q_m \end{bmatrix} = \begin{bmatrix} \text{green box} & T_k \\ & \text{red box } \Theta_{m-k} \end{bmatrix}$$

Our insight is a special *arrowhead matrix* created from the k desired eigenpairs (θ_i, y_i) :

$$D_{k+1} = \begin{bmatrix} \theta_1 & & & \beta y_{m,1} \\ & \ddots & & \vdots \\ & & \theta_k & \beta y_{m,k} \\ \beta y_{m,1} & \dots & \beta y_{m,k} & \star \end{bmatrix} \quad (\beta \neq 0, \star \in \mathbb{R}).$$

Various methods (Householder, Givens, etc.) can *tridiagonalize* D_{k+1} :

$$\begin{bmatrix} \text{pink box } Q_k^T \\ 1 \end{bmatrix} \begin{bmatrix} \text{diagonal line} \\ D_{k+1} \\ \text{horizontal line} \end{bmatrix} \begin{bmatrix} \text{pink box } Q_k \\ 1 \end{bmatrix} = \begin{bmatrix} \text{diagonal lines} \\ T_{k+1} \end{bmatrix}$$

Arrowhead Conversion

$$\begin{bmatrix} Q_k^T \\ 1 \end{bmatrix} \begin{bmatrix} D_{k+1} \\ \text{---} \end{bmatrix} \begin{bmatrix} Q_k \\ 1 \end{bmatrix} = \begin{bmatrix} \text{---} \\ T_{k+1} \end{bmatrix}$$

Truncate the first k rows & columns:

$$\begin{bmatrix} Q_k^T \end{bmatrix} \begin{bmatrix} \diagdown \Theta_k \diagup \end{bmatrix} \begin{bmatrix} Q_k \end{bmatrix} = \begin{bmatrix} \text{---} \\ T_k \end{bmatrix}$$

Arrowhead Conversion

$$\begin{bmatrix} Q_k^T \\ 1 \end{bmatrix} \begin{bmatrix} D_{k+1} \\ \hline \end{bmatrix} \begin{bmatrix} Q_k \\ 1 \end{bmatrix} = \begin{bmatrix} \hline \hline \hline \\ T_{k+1} \end{bmatrix}$$

Truncate the first k rows & columns:

$$\begin{bmatrix} Q_k^T \end{bmatrix} \begin{bmatrix} \diagdown \Theta_k \diagup \end{bmatrix} \begin{bmatrix} Q_k \end{bmatrix} = \begin{bmatrix} \hline \hline \hline \\ T_k \end{bmatrix}$$

Utilizing $T_m \begin{bmatrix} Y_k & Y_{m-k} \end{bmatrix} = \begin{bmatrix} Y_k & Y_{m-k} \end{bmatrix} \begin{bmatrix} \Theta_k & \\ & \Theta_{m-k} \end{bmatrix}$:

$$\begin{bmatrix} Y_k Q_k & Y_{m-k} \end{bmatrix}^T \begin{bmatrix} \hline \hline \hline \\ T_m \end{bmatrix} \begin{bmatrix} Y_k Q_k & Y_{m-k} \end{bmatrix} = \begin{bmatrix} \hline \hline \hline \\ T_k \end{bmatrix} \begin{bmatrix} \hline \hline \hline \\ \Theta_{m-k} \end{bmatrix}$$

Structure of $Y_k Q_k$

$$\begin{bmatrix} Y_k Q_k & Y_{m-k} \end{bmatrix}^T \begin{bmatrix} \diagdown \diagup \\ T_m \end{bmatrix} \begin{bmatrix} Y_k Q_k & Y_{m-k} \end{bmatrix} = \begin{bmatrix} \begin{matrix} \diagdown \diagup \\ T_k \end{matrix} & \\ & \begin{matrix} \diagdown \diagup \\ \oplus_{m-k} \end{matrix} \end{bmatrix}$$

Theorem 2.4 (Baglama, Monette, Perovic 2026)

The $m \times k$ matrix $\vec{Y}_k := Y_k Q_k$ has the form

$$\vec{Y}_k = \begin{bmatrix} \left. \begin{matrix} \diagdown \diagup \\ \end{matrix} \right\} p+1 \\ \diagdown \diagup \end{bmatrix} \quad (\text{where } p = m - k).$$

Connection to QR Algorithm

Alternatively, use the QR algorithm with $\underbrace{\{\theta_{k+1}, \dots, \theta_m\}}_{\text{undesired!}}$ as shifts.

$$\begin{bmatrix} Q_k^+ & Y_{m-k} \end{bmatrix}^T \begin{bmatrix} \diagdown & & \\ & \diagdown & \\ & & \diagdown \end{bmatrix} \begin{bmatrix} Q_k^+ & Y_{m-k} \end{bmatrix} = \begin{bmatrix} T_k^+ & \Theta_{m-k} \end{bmatrix}$$

T_m

Connection to QR Algorithm

Alternatively, use the QR algorithm with $\underbrace{\{\theta_{k+1}, \dots, \theta_m\}}_{\text{undesired!}}$ as shifts.

$$\begin{aligned}
 & \begin{bmatrix} Q_k^+ & Y_{m-k} \end{bmatrix}^T \begin{bmatrix} \diagup \diagdown \\ T_m \end{bmatrix} \begin{bmatrix} Q_k^+ & Y_{m-k} \end{bmatrix} = \begin{bmatrix} T_k^+ & \Theta_{m-k} \end{bmatrix} \\
 & \begin{bmatrix} Y_k Q_k & Y_{m-k} \end{bmatrix}^T \begin{bmatrix} \diagup \diagdown \\ T_m \end{bmatrix} \begin{bmatrix} Y_k Q_k & Y_{m-k} \end{bmatrix} = \begin{bmatrix} T_k & \Theta_{m-k} \end{bmatrix}
 \end{aligned}$$

Connection to QR Algorithm

Alternatively, use the QR algorithm with $\underbrace{\{\theta_{k+1}, \dots, \theta_m\}}_{\text{undesired!}}$ as shifts.

$$\begin{aligned}
 & \begin{bmatrix} Q_k^+ & Y_{m-k} \end{bmatrix}^T \begin{bmatrix} \diagdown & \diagup \\ \diagdown & \diagup \\ \diagdown & \diagup \end{bmatrix} \begin{bmatrix} Q_k^+ & Y_{m-k} \end{bmatrix} = \begin{bmatrix} T_k^+ & \\ & \ominus_{m-k} \end{bmatrix} \\
 & \begin{bmatrix} Y_k Q_k & Y_{m-k} \end{bmatrix}^T \begin{bmatrix} \diagdown & \diagup \\ \diagdown & \diagup \\ \diagdown & \diagup \end{bmatrix} \begin{bmatrix} Y_k Q_k & Y_{m-k} \end{bmatrix} = \begin{bmatrix} T_k & \\ & \ominus_{m-k} \end{bmatrix}
 \end{aligned}$$

Theorem 2.6 (Baglama, Monette, Perovic 2026)

Arrowhead method with k eigenpairs = QR algorithm with $m - k$ shifts:

$$T_k = S^{-1} T_k^+ S, \quad \vec{Y}_k = Q_k^+ S, \quad S = \text{diag}(\pm 1, \dots, \pm 1).$$

Examples

Numerical examples for **deflation** of $p = m - k$ eigenpairs.

Input: Tridiagonal T with eigenpairs $TX = X\Lambda$.

Arrowhead Method (T, k)

- Create D_{k+1} with desired eigenpairs.
- Reduce to $T_k = Q_k^T D_k Q_k$.
- $Q = X_k Q_k$.
- $\tilde{T} = Q^T T Q \in \mathbb{R}^{k \times k}$.

Implicit QR Method (T, p)

- Apply p shifts of undesired eigenvalues to T .
- Accumulate orthogonal matrices in Q .
- $\tilde{T} = Q^T T Q \in \mathbb{R}^{k \times k}$.

$$\begin{bmatrix} Q \end{bmatrix}^T \begin{bmatrix} \text{tridiagonal } T \end{bmatrix} \begin{bmatrix} Q \end{bmatrix} = \begin{bmatrix} \text{tridiagonal } \tilde{T} \end{bmatrix}$$

Examples

- Wilkinson tridiagonal. Eigenvalues are very clustered.
 - Size: 41, shifts: $p = m - k = 20$ smallest eigenvalues.
- Fann tridiagonal. Applications in computational quantum chemistry; a “difficult” test matrix in LAPACK’s eigensolvers.
 - Size: 120, shifts: $p = m - k = 60$ smallest eigenvalues.

Examples

- Wilkinson tridiagonal. Eigenvalues are very clustered.
 - Size: 41, shifts: $p = m - k = 20$ smallest eigenvalues.
- Fann tridiagonal. Applications in computational quantum chemistry; a “difficult” test matrix in LAPACK’s eigensolvers.
 - Size: 120, shifts: $p = m - k = 60$ smallest eigenvalues.

	$\left\ \text{eig}(T(1:k, 1:k)) - \text{eig}(\tilde{T}) \right\ $	$\left\ \tilde{T} - Q^T T Q \right\ $
Wilkinson Matrix		
Arrowhead	2.5×10^{-14}	5.7×10^{-14}

Fann Matrix		
Arrowhead	1.6×10^{-14}	4.4×10^{-15}
Implicit QR	1.7	4×10^{-15}

Restarting the Lanczos Algorithm

Introduction

Goal: Compute a few (k) *eigenpairs* $\{(\lambda_i, x_i)\}_{i=1}^k$ of a large, sparse, symmetric $A \in \mathbb{R}^{n \times n}$.

Utilize the Lanczos Algorithm — project A onto an $m \ll n$ dimensional subspace:

$$AP_m = P_m T_m + f e_m^T$$

$$\begin{bmatrix} & & \\ & A & \\ & & \end{bmatrix} \begin{bmatrix} \\ P_m \\ \end{bmatrix} = \begin{bmatrix} \\ P_m \\ \end{bmatrix} \begin{bmatrix} \diagdown \diagup \\ T_m \\ \diagup \diagdown \end{bmatrix} + \begin{bmatrix} \text{gray box} \\ f \end{bmatrix}.$$

Restart Methods

$$\begin{bmatrix} A \end{bmatrix} \begin{bmatrix} P_m \end{bmatrix} = \begin{bmatrix} P_m \end{bmatrix} \begin{bmatrix} \text{diagonal lines} \\ T_m \end{bmatrix} + \begin{bmatrix} \text{gray box} \\ f \end{bmatrix}$$

Eigenpairs $\{(\theta_i, y_i)\}_{i=1}^m$ of T_m are used to approximate those of A :

$$T_m y_i = \theta_i y_i \quad \Rightarrow \quad A(P_m y_i) = \theta_i(P_m y_i) + f e_m^T y_i.$$

We call $(\theta_i, P_m y_i)$ a **Ritz pair** of A .

Restart Methods

$$\begin{bmatrix} A \end{bmatrix} \begin{bmatrix} P_m \end{bmatrix} = \begin{bmatrix} P_m \end{bmatrix} \begin{bmatrix} \diagdown \\ T_m \end{bmatrix} + \begin{bmatrix} \text{gray box} \\ f \end{bmatrix}$$

Eigenpairs $\{(\theta_i, y_i)\}_{i=1}^m$ of T_m are used to approximate those of A :

$$T_m y_i = \theta_i y_i \Rightarrow A(P_m y_i) = \theta_i(P_m y_i) + f e_m^T y_i.$$

We call $(\theta_i, P_m y_i)$ a **Ritz pair** of A .

If the residuals $\|f\| \cdot |y_{m,i}|$ are too large, Lanczos can be restarted:

Thick Restarts

- MATLAB post-2016
- Krylov-Schur – Stewart 2002
- Thick Restart Lanczos
(TRL)–Wu & Simon 2000

Implicit Restarts

- MATLAB pre-2016
(Octave, ARPACK)
- IRA – Sorensen 1992
- Implicit Restart Lanczos (IRL)

Restart Methods

$$\begin{bmatrix} A \end{bmatrix} \begin{bmatrix} P_m \end{bmatrix} = \begin{bmatrix} P_m \end{bmatrix} \begin{bmatrix} \text{diagonal} \\ T_m \end{bmatrix} + \begin{bmatrix} \text{arrowhead} \\ f \end{bmatrix}$$

Eigenpairs $\{(\theta_i, y_i)\}_{i=1}^m$ of T_m are used to approximate those of A :

$$T_m y_i = \theta_i y_i \Rightarrow A(P_m y_i) = \theta_i(P_m y_i) + f e_m^T y_i.$$

We call $(\theta_i, P_m y_i)$ a **Ritz pair** of A .

If the residuals $\|f\| \cdot |y_{m,i}|$ are too large, Lanczos can be restarted:

Thick Restarts

- MATLAB post-2016
- Krylov-Schur – Stewart 2002
- Thick Restart Lanczos
(TRL)–Wu & Simon 2000

Implicit Restarts

- MATLAB pre-2016
(Octave, ARPACK)
- IRA – Sorensen 1992
- Implicit Restart Lanczos (IRL)

Equivalence has been known: Wu & Simon 2000, Morgan 2004, etc.

Goal: A stronger connection using arrowhead matrices.

Thick Restarts (TRL) and Implicit Restarts (IRL)

Until convergence ...

1. Generate m -Lanczos factorization: $AP_m = P_m T_m + fe_m^T$.
2. Compute Ritz pairs: $\{(\theta_i, x_i)\}_{i=1}^m$ $x_i = P_m y_i$ and $T_m y_i = \theta_i y_i$.
3. “Restart” with k “desired” eigenpairs; build new m -Lanczos.

Thick Restart Lanczos (TRL)

Initialization:

$$\begin{bmatrix} A \end{bmatrix} \begin{bmatrix} P_m \end{bmatrix} = \begin{bmatrix} P_m \end{bmatrix} \begin{bmatrix} T_m \end{bmatrix} + \begin{bmatrix} \text{gray rectangle} \end{bmatrix} \begin{bmatrix} f \end{bmatrix}$$

Repeat:

$$\begin{bmatrix} A \end{bmatrix} \begin{bmatrix} \end{bmatrix} = \begin{bmatrix} \end{bmatrix} \begin{bmatrix} \text{yellow square} \end{bmatrix} + \begin{bmatrix} \text{gray rectangle} \end{bmatrix}$$

$$\begin{bmatrix} A \end{bmatrix} \begin{bmatrix} \end{bmatrix} = \begin{bmatrix} \end{bmatrix} \begin{bmatrix} \text{yellow square} \end{bmatrix} + \begin{bmatrix} \text{gray rectangle} \end{bmatrix}$$

TRL – Contraction Step

“Restart” with desired Ritz vectors $P_m Y_k$. Let $p_{m+1} = f/\beta$, $\beta = \|f\|$.

$$D_{k+1} := \begin{bmatrix} \theta_1 & & & \beta y_{m,1} \\ & \ddots & & \vdots \\ & & \theta_k & \beta y_{m,k} \\ \beta y_{m,1} & \dots & \beta y_{m,k} & * \end{bmatrix}$$

TRL – Contraction Step

“Restart” with desired Ritz vectors $P_m Y_k$. Let $p_{m+1} = f/\beta$, $\beta = \|f\|$.

$$D_{k+1} := \begin{bmatrix} \theta_1 & & \beta y_{m,1} \\ & \ddots & \vdots \\ & & \theta_k & \beta y_{m,k} \\ \beta y_{m,1} & \dots & \beta y_{m,k} & * \end{bmatrix}$$

... yielding a “not quite”-Lanczos factorization!

$$\begin{bmatrix} A \end{bmatrix} \begin{bmatrix} P_m Y_k & p_{m+1} \end{bmatrix} = \begin{bmatrix} P_m Y_k & p_{m+1} \end{bmatrix} \begin{bmatrix} \diagdown & \\ & D_{k+1} \end{bmatrix} + \begin{bmatrix} \text{shaded block} & \vec{f} \end{bmatrix}$$

$\vec{f} = \vec{t}_{k+1,k} p_{m+1}$

Updating Lanczos Factorization

Tridiagonalize the arrowhead matrix D_{k+1} , with methods from before:

$$\begin{bmatrix} \vec{Q}_k^T \\ \hline 1 \end{bmatrix} \begin{bmatrix} \diagdown & & \\ & D_{k+1} & \\ \hline & & \diagup \end{bmatrix} \begin{bmatrix} \vec{Q}_k \\ \hline 1 \end{bmatrix} = \begin{bmatrix} \diagdown & & \\ & \vec{T}_{k+1} & \\ \hline & & \diagup \end{bmatrix}$$

Multiply by $\vec{Q}_{k+1}$ and truncate, obtaining k -Lanczos factorization:

$$\begin{bmatrix} A \\ \hline \end{bmatrix} \begin{bmatrix} P_m Y_k \vec{Q}_k \\ \hline \end{bmatrix} = \begin{bmatrix} P_m Y_k \vec{Q}_k \\ \hline \end{bmatrix} \begin{bmatrix} \diagdown & & \\ & \vec{T}_k & \\ \hline & & \diagup \end{bmatrix} + \begin{bmatrix} \text{gray box} \\ \hline \vec{f} \end{bmatrix}$$

$\vec{f}$ is not changed!

TRL + Arrowhead Conversion

$$\begin{bmatrix} A \end{bmatrix} \begin{bmatrix} P_m \end{bmatrix} = \begin{bmatrix} P_m \end{bmatrix} \begin{bmatrix} T_m \end{bmatrix} + \begin{bmatrix} \text{gray rectangle} \end{bmatrix} \begin{bmatrix} f \end{bmatrix}$$

$$\begin{bmatrix} A \end{bmatrix} \begin{bmatrix} \end{bmatrix} = \begin{bmatrix} \end{bmatrix} \begin{bmatrix} \text{pink square} \end{bmatrix} + \begin{bmatrix} \text{gray rectangle} \end{bmatrix} \begin{bmatrix} \end{bmatrix}$$

$$\begin{bmatrix} A \end{bmatrix} \begin{bmatrix} \end{bmatrix} = \begin{bmatrix} \end{bmatrix} \begin{bmatrix} \text{pink square} \end{bmatrix} \begin{bmatrix} T_m \end{bmatrix} + \begin{bmatrix} \text{gray rectangle} \end{bmatrix} \begin{bmatrix} \end{bmatrix}$$

Implicit Restart Lanczos (IRL) — Exact Shifts

1. Generate m -Lanczos factorization: $AP_m = P_m T_m + f e_m^T$.
2. Apply shifts $\theta_{k+1}, \dots, \theta_m$ via the QR algorithm to T_m :

$$T_m^+ = Q_m^{+T} T_m Q_m^+ = \left[\begin{array}{c|c} \text{green box} & T_k^+ \\ \hline & \text{red arrow labeled } \ominus_{m-k} \end{array} \right]$$

3. Truncate to size k ; obtain a new **start vector**.

$$AP_m Q_k^+ = P_m Q_k^+ T_k^+ + \textcolor{blue}{q}_{m,k}^+ f e_k^T.$$

4. Extend to a new m -Lanczos factorization.

Implicit Restart Lanczos (IRL) — Exact Shifts

1. Generate m -Lanczos factorization: $AP_m = P_m T_m + f e_m^T$.
2. Apply shifts $\theta_{k+1}, \dots, \theta_m$ via the QR algorithm to T_m :

$$T_m^+ = Q_m^{+T} T_m Q_m^+ = \left[\begin{array}{c|c} \text{green box} & T_k^+ \\ \hline & \text{red arrow labeled } \ominus_{m-k} \end{array} \right]$$

3. Truncate to size k ; obtain a new **start vector**.

$$AP_m Q_k^+ = P_m Q_k^+ T_k^+ + q_{m,k}^+ f e_k^T.$$

4. Extend to a new m -Lanczos factorization.

... sound familiar?

Mathematical Equivalence

$$\text{TRL} \quad AP_m \vec{Y}_k = P_m \vec{Y}_k \vec{T}_k + \vec{t}_{k+1,k} p_{m+1} e_k^T$$

$$\text{IRL} \quad AP_m Q_k^+ = P_m Q_k^+ T_k^+ + q_{m,k}^+ f e_k^T$$

Theorem (Baglama, Monette, Perovic 2026)

TRL	=	IRL
with arrowhead reduction		with exact shifts

That is, there exists $S = \text{diag}(\pm 1, \dots, \pm 1)$ such that

$$\vec{Y}_k = Q_k^+ S, \quad \vec{T}_k = S^{-1} T_k^+ S, \quad \vec{t}_{k+1,k} = \pm \beta q_{m,k}^+$$

meaning that $\text{TRL} = \text{IRL} \cdot S$.

This is a **stronger** result with **no Krylov subspace** arguments!

Key Takeaways

- The QR algorithm with multiple shifts can fail to deflate eigenvalues.
- The “arrowhead method” is a significant improvement to this task.
- Thick Restart Lanczos with arrowhead reduction is **equal** to Implicit Restart Lanczos with exact shifts (not just *equivalent*!)
- An Extension: Replace “Lanczos” with “GKLB” and use a half-arrowhead matrix to show equivalence between thick and implicit GKLB for SVD computations.
